Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of document should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO and IEC shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents) or the IEC list of patent declarations received (see <http://patents.iec.ch>).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT) see www.iso.org/iso/foreword.html.

This document was prepared by Joint Technical Committee ISO/IEC JTC 1, *Information technology*, Subcommittee SC 36, *Information technology for learning, education and training*.

A list of all parts in the ISO/IEC 24751 series can be found on the ISO website.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at www.iso.org/members.html.

Introduction

For individualized accessibility, the needs and preferences of individual users need to be described in a concise and machine-readable manner. User interfaces and their components can then read such personal "AfA preference statements" and accommodate them in their adaptations. In addition, other aspects of the context of use need to be described so that user interfaces and their components can take the user's tasks, their equipment and their environment into account. Also, user interface resources need to be described so that "AfA services" can identify the most appropriate resources for a specific context of use.

For all descriptions, vocabularies are instrumental to allow for a strict semantic and machine-readability. ISO/IEC DIS 24751-1¹⁾ introduces an AfA concept registry for "AfA concepts" for the description of AfA preference statements, other aspects of the context of use and user interface resources. For each AfA concept, a concept record contains a globally unique identifier and other characteristics of the AfA concept.

An AfA concept registry needs to be globally accessible through a well-defined API and format rules need to exist for the exchange of AfA concept records. This document specifies a RESTful API for an AfA concept registry service (a.k.a. registry server) and a JSON format for AfA concept records to be exchanged through the AfA concept registry API.

The following use cases are meant to illustrate the benefits of a standardized API and AfA concept record format. This list of use cases is not meant to restrict further uses of this document in any way.

- A person using an AfA concept registry (e.g., a developer of an assistive technology solution) registers an AfA concept on a registry server. This can be facilitated by either a web interface of the registry or by a third-party development application (e.g., an integrated development tool) running on the person's computer. The third-party development application has some advantages over the web interface since it allows for a tighter integration of development platform and registry server. It requires the definition of a concept registry API and of the format an AfA concept record.
- An infrastructure component (e.g., a tool for setting up AfA preference statements or an AfA service) looks up an AfA concept on a registry server. Thus, the definition of an AfA concept can be presented to the user or the range of allowed values of an AfA concept can be considered for the identification of matching AfA resources.
- A syntax checker (e.g., special lint tool) verifies the contents of a new AfA preference statement by validating against the AfA concept records on a registry server. By this procedure, invalid values for AfA concepts can be detected. In case of an invalid AfA preference statement, the syntax checker can notify the user about the error or make automatic corrections.

NOTE 1 A syntax checker could be part of a service managing AfA preference statements, checking everything incoming AfA preference statement for syntax errors before storing it.

- Two services managing AfA preference statements synchronize their AfA preference statements. This could be a full synchronization over all contained AfA preference statements, or it could affect only a part of the statements. To avoid the distribution of invalid content, incoming statements can be verified against the AfA concept records of an AfA registry server (e.g., to detect invalid values), and erroneous statements can be skipped or automatically corrected.
- Two AfA registry servers synchronize their entries. This could be a full synchronization over all contained AfA concept records or it could affect only a part of the entries.

1) 2nd Edition under development. Stage at time of publication: ISO/IEC DIS 24751-1:2018.

NOTE 2 While ISO/IEC DIS 24751-1 leaves open whether there is a single registry server or multiple registry servers, it is possible to run multiple registry servers globally. Some organizations have built, for security and privacy reasons, self-contained digital infrastructures (such as intranets) with only very few and well-defined gateways to the external internet. Such organizations would possibly prefer to have their own registry server running in their infrastructure, and have it synchronize with some global registry server in a secured way from time to time. Also, organizations that develop adaptive user interfaces or assistive technology solutions would likely want to have their own registry server for experimentation purposes.

Part 4: Registry server API

1 Scope

This document specifies an API in support of ISO/IEC DIS 24751-1. In particular, this document specifies:

- a data format (in JSON) for the exchange of registry entries (AfA concept records) between registry servers;
- a set of RESTful operations for AfA registry servers to allow for the manipulation of AfA concept registry entries by external clients other than server-internal web interfaces.
